

# SLT Projection Questionnaire

## Compiler's Guide

2021/2022 submission cycle

International  
Energy Agency

iea

This document provides information and instructions for data compilers regarding the International Energy Agency (IEA) *SLT Projection Questionnaire* for the 2021/22 submission cycle.

The 2021/22 submission will pilot an upgraded version of the questionnaire; please share with [slt@iea.org](mailto:slt@iea.org) any questions or comments you may have on this document or the underlying data compilation, as soon as they emerge.

## Table of Contents

SLT Projection Questionnaire .....	1
1. Introduction .....	3
2. Changes from last cycle.....	5
New compiler's guide .....	5
Scenario(s) description .....	5

# 1. Introduction

Considering the complexities of the related socio-economic factors, energy policy and planning requires adopting a long-term perspective. Building energy infrastructure takes time and decisions made right now can shape the structure and outcomes of our choices for many decades. It takes a considerable amount of time for new energy technologies to develop and mature and reach their desired market share. Similarly, the use of energy has impacts on the ecosystem over a long period expanding from decades to centuries and it can take years for the effects of energy policy responses to be appreciated. Hence, long-term perspectives are essential in analysing and planning the energy system and its corresponding socio-economic and environmental impacts in order to accelerate energy transitions.

National projections will become more and more relevant within the evolving landscape of energy transitions. Governments and other data users benefit from these projections for planning and monitoring the progress towards national energy and climate targets, refining energy models and informing policy reviews and recommendations. The data submitted to the IEA in this questionnaire are the basis for an international compilation of national projections and are disseminated through the [Projections: Energy Policies of IEA Countries](#) database.

In an effort to keep the data collection pertinent to evolving policy priorities while minimizing the additional burden on data providers, IEA initiated a consultation with member countries in summer 2021, discussing opportunities for improving the Standing Group on Long-Term Co-operation (SLT) projections questionnaire for the upcoming cycles. Following constructive responses from data providers, this effort was broadly communicated with the country delegates in the SLT Committee held in December 2021, receiving much positive feedback.

Subsequent to the consensus among member countries on the value of enhancing the relevance of projections data collection and its visibility, IEA is running during the 2021/22 cycle a pilot data collection with the new version of the questionnaire, to assess the impact of the updates, and collect relevant feedback from data providers. The deadline for data submission has been extended to mid-April 2022 to accommodate any additional efforts required, although we would welcome earlier feedback and responses. The main updates to the questionnaire are summarized in *Section 2 - Changes from last edition* below. Based on further feedback from data compilers and users, the pilot may require further refinement for the upcoming cycles.

To ensure clarity to users, data compilers are requested to select the specific scenario category that best corresponds to the national scenario underlying the reported data; additionally, projections corresponding to different scenarios can be reported in different files. Please refer to *Section 4 - Guidelines for the completion of the questionnaire* for more details.

The projections refer to three years: 2030, 2040 and 2050. To support compilation, the IEA will prefill energy time series of balances for the last three historical years, based on previous country reporting.

Starting with this cycle, the questionnaire also covers few additional items not yet collected in the annual questionnaires in order to compile data on fuel/technologies which are expected to gain importance in the energy systems. This includes: accounting of hydrogen and synthetic fuels; the ambient heat captured by heat pumps; and the emissions savings from carbon capture, utilization and storage (CCUS) across sectors.

The list of sheets and tables to be filled is presented in *Section 3 – Content of the questionnaire*.

## 2. Changes from last cycle

This section presents the changes of the questionnaire structure and content as compared to previous submission cycles. The upgrade in design, meant to enhance data relevance without adding burden to data providers, integrated input from the 2021 consultation with data providers.

### New compiler's guide

To facilitate data compilation, we have designed this Compiler's Guide as a guidance on how to fill the questionnaire and use its functionalities. The guide includes a clear description of the questionnaire structure and all its individual data and visualisation elements; as well as new methodological explanations on the energy balance concept and on the way of categorising scenarios – both being key to a correct data compilation and interpretation.

### Scenario(s) description

Starting with this cycle, data compilers have the option of submitting different files, each with projections corresponding to one scenario category, if available at national level, for example corresponding to different pathways (business as usual, more or less ambitious targets, etc).

To assist data compilers in categorising the national scenario used for each of the submissions, the "**Scenario**" sheet includes a menu and a few qualitative questions. Understanding the category of the scenarios and their underlying methodologies is essential to a correct interpretation of data and facilitates comparison and analysis.

For guidance on categories of scenarios and how to fill the sheet, please refer to *Section 4 – Guidelines for compiling the questionnaire*.

### Integration of data for new technologies

The simplified energy balance of Table 1 has been extended to allow for reporting of few additional energy products and flows that may become more relevant in future energy systems, as listed below. Note that most additional data are being requested as information outside the traditional energy balance table, until a harmonized methodology for reporting those technologies within the energy balance is adopted in international energy statistics.

Additionally, a new table (Table 3) is now requesting information on carbon capture, utilization and storage (CCUS), directly in emissions units.

The main changes are listed below. For more details on how to report the additional categories please refer to *Section 4 – Guidelines for compiling the questionnaire*.

#### Products in Table 1

- **Non-renewable wastes**

To allow calculation of renewable shares, the “*Combustible renewables and waste*” category has been split into “*Biofuels and renewable waste*” and “*Non-renewable waste*”. This disaggregation will allow deriving relevant indicators such as the share of renewables in energy supply and consumption, as well as in power generation.

- **Memo: Offshore wind**

The memo product “*Offshore Wind*” has been added. Please note that this amount should be included also as a subcomponent of the “*Wind*” element within the balance. With the projected prominent role of offshore wind in the upcoming years, reporting the corresponding data in a disaggregated manner will be beneficial in analysing the effects of policy levers and market developments specific to offshore generation.

- **Memo: Hydrogen & Synthetic fuels**

The memo product “*Hydrogen & Synthetic fuels*” has been added. Although quantities may be currently negligible, the potential prominent role of these fuels in the upcoming decades requires a more clear accounting framework.

Note that the current IEA balance format allows for reporting hydrogen and synthetic fuels supply and consumption within other energy carriers. However, it does not yet include specific categories for reporting hydrogen and synthetic fuels separately. The addition of this item outside the balance provides a mean to enhance the granularity for reporting supply and demand of these energy carriers without a risk of double counting or breaking the balance, until a harmonized methodology for reporting is adopted in international energy statistics.

For details on how to report under hydrogen and synthetic fuels within the balance and as separate products in this memo product please refer to *Section 4 – Guidelines for the completion of the questionnaire*.

- **Memo: Heat pump**

The memo product “*Heat pump*” has been added to the table. Note that there were existing means of reporting the data corresponding to industrial heat pumps who sell heat to third parties in the existing IEA balance. However, data corresponding to small-scale heat pumps mainly operated within the residential sector where heat is not sold are excluded from the balance table.

Heat pumps are projected to be one of the key technologies for decarbonisation of end-use heating services especially in the residential sector. The addition of this memo item allows the reporting of the combined impact of all types of heat pumps and not only the large-scale units used for selling heat. For details on how to report heat pumps that sell heat within the balance and all heat plans in this memo product please refer to *Section 4 – Guidelines for the completion of the questionnaire*.

## Flows in Table 1

- **Of which: Commercial and public services**

This flow has been added to allow reporting of the consumption of energy products specifically in the commercial and public services sectors. This data is of great value as together with the reported data under the residential sector will provide an estimate for

the energy consumption in the buildings sector as one of the main end-use sectors in long-term energy planning and policies.

For details on how to report under this flow please refer to *Section 4 – Guidelines for the completion of the questionnaire*.

- **Memo: Input to Hydrogen & Synthetic fuels production**

Similar to the products, a new memo flow has been added to the balance to allow dedicated reporting of fuel inputs in production of hydrogen and synthetic fuels.

For details on how to report under this memo flow please refer to *Section 4 – Guidelines for the completion of the questionnaire*.

- **Memo: Input to Heat pump**

The memo flow “*Input to Heat pump*” was included to enable the reporting of electricity and heat (e.g., recovered heat) input to heat pumps. The addition of this memo item allows the reporting of all heat pumps and not only large-scale units used for selling heat.

For details on how to report under this memo flow please refer to *Section 4 – Guidelines for the completion of the questionnaire*.

- **Memo: Electrical Capacities**

The memo flow “*Electrical Capacities*” has been added to allow projecting the electrical capacities of both electricity only and CHP plants for various fuels and technologies. This data will be helpful as would allow estimating the generation capacity factors as well as useful indicators such as share of renewables and low carbon sources in total installed capacities providing insight on the evolving power generation infrastructure.

For details on how to report under this memo flow please refer to *Section 4 – Guidelines for the completion of the questionnaire*.

## Carbon capture, utilization and storage (CCUS) in Table 3

Decarbonizing the energy system can only be achieved with a broad suite of technologies. Carbon capture, utilization and storage (CCUS) is considered a key component of the future technology mix as it may allow reducing emissions across hard-to-abate sectors. Hence, CCUS may become a critical part of long-term strategies for achieving energy and climate targets.

A new table has been included to allow reporting of emission savings through CCUS (Table 3) as the mass of CO<sub>2</sub> expected to be captured via CCUS technologies across sectors.

For details on how to report in this table please refer to *Section 4 – Guidelines for compiling the questionnaire*.

## Simplification of the reporting

In order to minimize the burden on data providers, a number of simplifications have been introduced as compared to previous submissions, which are considered not to impact strongly the effectiveness of this data collection going forward.

## Supply side simplification

The supply side reporting in Table 1 has been simplified by removing the requirement to report “*stock change*” figures. The supply side of the balance includes “*production*”, “*imports*” and “*exports*”, “*International marine bunkers*” and “*International aviation bunkers*”. Note that the rows corresponding to the non-mandatory flow above have been kept in the mini balance for the pilot, to minimize the impacts of changing the reporting structure and to still allow optional reporting of these data.

## Removal of dedicated coal table

In order to reduce the burden on data providers, the table previously used to report a detailed breakdown of coal production, imports and exports by type has been removed from the questionnaire. Note that the figures corresponding to total coal production, imports and exports should still be reported in Table 1.

## Removal of provisional year table

The requirement to report balances for the “provisional year” (year 2020 for this cycle) has been lifted. Energy balances projections need to be reported for 2030, 2040 and 2050. Due to the relevance of 2050 in the context of various national targets (including NDCs and net zero targets) and international commitments, please note that the reporting for this year is no longer optional. Note that this simplification corresponds to Table 1 and “provisional year” data corresponding to Table 2 and Table 3 are part of the reporting.

## New import/export functionalities in the tool

New functionalities have been added to questionnaire in order to help the data providers and users and enhance the relevance of the content. They refer to options for importing and exporting data in a more structured way through CSV files.

## Importing data through CSV

The data providers can load data from a CSV file to fill the tables for projections. The CSV import function has been placed in a new sheet called the “**Data Import & Export**” tab.

For details on how to use the CSV import function please refer to *Section 4 – Guidelines for compiling the questionnaire*.

## Exporting data as CSV

Similarly, data providers can export the data corresponding to projections in a CSV format. This includes the respective data included in all three tables. The CSV export function has been placed in a new sheet called the “**Data Import & Export**” tab.

For details on how to use the CSV export function please refer to *Section 4 – Guidelines for compiling the questionnaire*.

## Improving validation through indicators and graphics

A new functionality allows to populate various indicators and produce graphics based on the reported data, to support data validation and better tracking across historical and projection periods.

For details on the included indicators and the underlying methodology, please refer to *Section 5 – Energy transition indicators and graphs*.

## 3. Content of the questionnaire

This section describes the overall structure of the file, with focus on the sheets to be filled by data compilers: the scenario information and three statistical tables.

The file includes 12 worksheets with distinguish colour coding. When opening the file a sheet called the **"Start"** tab is visible. By clicking on the button on this sheet the remaining sheets are populated. The green tabs include the **"Intro"** sheet which provides general guidance on using the tool, the **"Data Import & Export"** sheet which provides functionalities to import and/or export data using CSVs as well as the **"2019"** sheet which is pre-filled by the IEA with the latest available historical data. The blue tabs correspond to the **"Energy Balance Time Series"** and **"Indicators"** sheets which are data visualization tools populated automatically providing a means to verify the submitted data.

The orange tabs are to be filled by the data compilers and include a **"Scenario"** sheet, **"Table 1"** sheets (for years 2030, 2040 and 2050), **"Table 2"** and **"Table 3"** sheets. This section includes visual representation of the above orange sheets. For details on how to report the data corresponding to each sheet please refer to *Section 4 – Guidelines for compiling the questionnaire*.

Please note that you can submit more than one file if you wish to share information corresponding to different scenario categories. In case of lack of updated projections, you can opt for copying previously submitted information in the statistical tables – please still ensure to provide the information on the underlying scenario.

### List of data inputs to be filled by compilers

Scenario:	Sheet to select the category of scenario and provide additional information
Table 1:	Energy balances for 2030, 2040 and 2050.
Table 2:	Supplementary data
Table 3:	Emission savings from CCUS

## Scenario sheet

<b>A. Scenario selection</b>	<b>Main category</b>	<b>Sub category</b>		
<p>The objective of this section is to assist in categorising the national scenario which is the basis of the projections data submitted in Tables 1, 2, 3.</p>	<div style="border: 1px solid black; padding: 2px;">Business as Usual</div>	<div style="border: 1px solid black; padding: 2px;">Please provide details in the table below</div>

## Table 2 – Supplementary data

	Historical Data				Data submission This Cycle			Last Cycle Projections			
	2017	2018	2019	2020	2030	2040	2050	2020.LC	2030.LC	2040.LC	2050.LC
GDP Growth Rates (%) <sup>(1)</sup>											
Population (Millions) <sup>(2)</sup>											
GDP (Billion USD 2015) <sup>(1)(2)</sup>											

(1) Refers to GDP in constant 2015 prices

(1) The annual growth rates (which refer to GDP in constant 2015 prices) should be calculated in the following way:

For 2019 report the GDP 2019/GDP 2018 annual rate.

For 2020 report the GDP 2020/GDP 2019 average annual rate.

For 2030 report the GDP 2030/GDP 2020 average annual rate.

For 2040 report the GDP 2040/GDP 2030 average annual rate.

For 2050 report the GDP 2050/GDP 2040 average annual rate.

(2) Before publication, the Secretariat will update the provisional 2020 GDP and population figures submitted with those published in OECD National Accounts.

**Table 3 – Emission savings from CCUS<sup>1</sup>**

Mass of CO2 captured (ktCO2)	Historical Data				Data submission This Cycle			Last Cycle Projections			
	2017	2018	2019	2020	2030	2040	2050	2020.LC	2030.LC	2040.LC	2050.LC
Total											
Natural gas processing											
Manufacturing											
Electricity and heat generation											
Hydrogen and synthetic fuel production											
Other											

---

<sup>1</sup> CCUS refers to carbon capture, utilization and storage

## 4. Guidelines for compiling the questionnaire

This section provides general guidelines for completing the questionnaire, from the scenario selection, to the new CSV import and export functionalities that can be used.

### Scenario categorisation

It is important to clearly communicate the purpose and context of the scenarios to avoid misinterpretation. The objective of this section is to assist data compilers in categorising the national scenario(s) which are the basis of the projections data submitted in the SLT questionnaire into one of the general categories described below. Understanding the category of the scenarios and their underlying methodology is of great value and facilitates the comparison and analysis of the submitted projections data.

Note that completion of the Scenario sheet is a requirement to ensure that data included in statistical tables are interpreted correctly; this information will be assessed during the questionnaire validation process.

It will be important to i) select a scenario category and ii) include key information on assumptions and methodologies, as well as links to available reference documentation, following the questions listed in the same sheet.

This section briefly introduces the typical scenario categories used across institutions for long-term energy planning, which correspond to the options to choose from in the "**Scenario**" sheet of the questionnaire.

#### 1. Business as usual scenarios:

The Business as Usual scenario category aims to capture scenarios that include only government policies which have been already adopted, and therefore project how the national energy landscape may evolve if the existing structures in energy supply and demand remain unchanged.

Scenarios with the Business as Usual category provide a baseline to compare alternative scenarios and a starting point for the understanding and analysis of the energy system by assuming a general continuation of historical trends into the future. The assumption is that the structure of the system remains unchanged or responds in pre-determined forms.

Examples include the European Commission's [EU Reference Scenario 2020](#), the IEA [Current Policies Scenario](#), the EIA's [Annual Energy Outlook Reference Case](#) and Canada's [Energy Future Current Policies Scenario](#).

#### 2. Stated policies scenarios:

The Stated Policy Scenario category aims to capture scenarios that take into account national climate and/or energy-related policies and measures which have been already

adopted by the government, together with pertinent policy proposals, announced commitments and plans which have been announced but are yet to be formally adopted.

A cautious view of the extent and timing to which policy proposals are projected to be implemented and objectives achieved are key in defining this type of scenarios. The aim of scenarios in this category is to provide a sense of where today's policy ambitions seem likely to drive the energy landscape.

In other words, this scenario type is a policy-based forecast, not a hypothetical scenario which is based on optimizing policy for a desired outcome.

It is typical to set out the gap in between the outcome of these types of scenario and targets such as efforts to limit global temperature increase to 1.5 C°, or wider Paris Agreement objectives. Examples include the IEA [Stated Policies Scenario \(STEPS\)](#) and the EU's [With Additional Measures \(WAM\)](#) scenarios.

### **3. Beyond stated policies (Aspirational) scenarios:**

Scenarios within this category set an energy pathway consistent with specific target(s) or other particular desired outcomes. By this means, they demonstrate what should be achieved across sectors and by various actors and by when, for the targets or outcomes to be achieved.

Examples include the European Commission's [REG](#) and [MIX](#) and the IEA [Net Zero Emissions by 2050 \(NZE\)](#) and [Sustainable Development \(SDS\)](#) scenarios.

The Aspirational scenarios may be divided into the following sub-categories:

#### **a) Achieving national targets scenarios:**

This type of scenarios could set out a pathway for the national (or regional) energy sector to achieve a specific target. For example a net zero scenario could set out a pathway for the national energy sector to achieve net zero emissions by a certain year. Or a Paris Agreement compliant scenario demonstrates a pathway consistent with the goal of limiting the global increase in temperature to 2 or 1.5°C (with a certain probability). Additionally, scenarios consistent with achieving certain sustainable development goals fall within this category.

#### **b) Achieving defined outcomes scenarios:**

This category of scenarios is consistent with defined outcomes rather than targets. Examples include scenarios consistent with achieving affordability of energy sources or long/short-term energy security purposes. Some scenarios could have multiple desired outcomes.

### **4. Other**

Scenarios which do not fall under any of the above general categories can be reported under this option. A short description of the methodology and model used and any underlying assumptions would be in this case essential to help with the clarity of the submitted projections data.

## Energy balance concepts

The energy balance is a presentation of the basic supply and demand data for all fuels in a manner which shows the main fuels together but separately distinguished and expressed in a common energy unit. The format of the IEA energy balance is based on the International Recommendations on Energy Statistics (IRES)<sup>2</sup>, which is a comprehensive framework on the scope of energy statistics including classifications, units and methodologies.

Energy data are generally collected independently across different commodities. Energy statistics are the simplest format to present all the data together, assembling the individual balances of all products, each expressed in its own physical unit (e.g. TJ for natural gas, kt for coal, etc). These are called commodity balances. However, energy products can be converted into one another through a number of transformation processes. Therefore, it is very useful to also develop one comprehensive national energy balance, to understand how products are transformed into one another, and to highlight the various relationships among them.

By presenting all the data in a common energy unit, the energy balance allows users to see the total amount of energy used and the relative contribution of each different source, for the whole economy and for each individual consumption sector; to compute the different fuel transformation efficiencies and to develop various indicators. The energy balance is a natural starting point to study the evolution of the domestic energy market, forecast energy demand, monitor impacts of energy policies and assess potential areas for action. The energy balance can also be used as a high-level check on the data accuracy, as large statistical differences in energy units, apparent energy gains or large losses in transformation processes, or large unexplained variations in shares or in high-level indicators may all indicate underlying data problems.

Table 1 is a simplified version of the IEA energy balance. An example of how to complete this table can be found by clicking the button "Sample latest historical year Energy Balance" included on the **"Intro"** sheet. This will direct you to a table which contains a simplified energy balance for the latest historical year. The data in this table have been prefilled by IEA based on the data submitted through the annual questionnaires, and can be used as a guide for filling Table 1 for projections.

This section outlines a general guide for completing the energy balances tables. Please refer to the IEA [World Energy Balances](#) documentation file for more details on the methodology for developing an energy balance based on fuel statistics.

---

<sup>2</sup> The report on International Recommendations on Energy Statistics (IRES) is available at <https://unstats.un.org/unsd/energy/mystats/methodology/ires/>.

## Table 1

### Columns

**Column A: "Coal"** includes: All coal and coal products both primary and derived, such as anthracite, coking coal, other bituminous coal, sub-bituminous coal, lignite, oil shale (primary product – however, note that the secondary product shale oil should be included under oil), patent fuel, coke oven coke (including semi-coke), gas coke, coal tar, brown coal briquettes as well as coke oven gas, gas works gas, blast furnace gas and other recovered gases. Note that peat should not be included in this column.

**Column B: "Peat"** includes peat burned for energy. Peat used for non-energy purposes should not be included.

**Column C: "Oil"** includes:

1. Crude oil, refinery feedstocks, natural gas liquids, and additives as well as non-crude hydrocarbons (tar sands, shale oils, etc.) and Orimulsion. **Imports and exports** of liquefied synthetic fuels should also be shown here.

2. Oil products including liquefied petroleum gas and refinery gas. Synthesised liquid hydrocarbons from other sources (e.g. hydrogen produced from natural gas, coal liquefaction) are transferred into the "Oil" column from the appropriate cells. For example, liquefied coal would be shown as coal consumed (and therefore negative) in *Cell JA* of Table 1 and as secondary oil production (and therefore positive) in *Cell JC*. Similarly hydrogen or other synthetic fuels produced from natural gas, would be shown as natural gas consumed in *Cell JD* and as secondary oil production in *Cell JC*.

**Column D: "Natural gas"** includes natural gas (excluding natural gas liquids) and import and exports of gaseous synthetic fuels including Hydrogen.

**Column E: "Nuclear "**. Please refer to the *Units and Conversion* section below.

**Column F: "Hydro"**. Please refer to the *Units and Conversion* section below. Note that only natural flow hydro generation should be included. The electricity losses associated with pumped storage electricity should be included in the quantities given in *Cell KM* "electricity-own use and losses".

**Column G: "Wind"**. Please refer to the *Units and Conversion* section below.

**Column H: "Geothermal"**. Please refer to the *Units and Conversion* section below.

**Column I: "Solar"**. Please refer to the *Units and Conversion* section below.

**Column J: "Tide, etc."**. Please refer to the *Units and Conversion* section below.

**Column K: "Biofuels and renewable waste"** includes solid biofuels, liquid biofuels, biogases and the renewable fraction of municipal waste. This includes primary solid biofuels, biogases, biogasoline, biodiesels, bio jet kerosene, other liquid biofuels, charcoal and renewable fraction of municipal waste produced by households, industry, hospitals and the tertiary sector that are collected by local authorities for incineration at specific installations.

**Column L: "Non-renewable waste"** includes industrial waste of non-renewable origin consisting of solid and liquid products (e.g. tyres) combusted directly, usually in specialised plants, to produce heat and/or power and the non-renewable fraction of municipal waste produced by households, industry, hospitals and the tertiary sector that are collected by local authorities for incineration at specific installations.

**Column M: "Electricity"** shows trade and final consumption in electricity (which is counted at the same heat value as electricity in final consumption i.e., 1 TWh = 0.086 Mtoe).

If hydrogen or synthetic fuels are produced through power to gas processes by consumption of electricity, and due to the current absence of these products in the main structure of the energy balance, the final consumption of these fuels can be reported under electricity, while accounting for the conversion losses. For example assuming a 3 Mtoe input of natural gas, 2/3 efficiency for electricity generation and 50% efficiency for the power to gas process, -3 should be reported in *Cell ID*, while 2 should be reported in *Cell IM*, -1 in *Cell KM* and 1 in *Cell RM* (assuming hydrogen consumption in household heating).

**Column N: "Heat"** permits the reporting of (a) the generation and consumption of heat for sale and (b) heat extracted from ambient air and water by heat pumps. The generation of heat for sale is reported as a transformation sector activity and the corresponding inputs should be included in the row **"Electricity, CHP & heat plants"**. Heat consumed at the point of production which is generated from fuels reported elsewhere in the balance, is not reported since this would be double-counting.

**Column O: "Total"** is the sum of columns (A) to (N). This column shows total energy supply (excluding international marine and aviation bunkers) and total final consumption.

**Column P: "Memo: Offshore wind"** is a memo category outside the current main structure of the energy balance. This product is a subcomponent of the **"Wind"** element. The Total wind production (including both onshore and offshore) is still to be reported under the product **"Wind"**. Please refer to the *Units and Conversion* section below.

**Column Q: "Memo: Hydrogen & synthetic fuels"** is a memo category outside the current main structure of the energy balance. This memo product has been added to allow reporting the data corresponding to hydrogen and synthetic fuels in a more visible manner. However, the reporting under this Memo category should not impact the existing means of reporting hydrogen and synthetic fuels supply and consumption as part of the main energy balance. Refer to *Column C (Oil)*, *Column D (Natural gas)* and *Column M (Electricity)* for details on how to report these products in the main structure of the energy balance.

For reporting under this memo category, production of hydrogen and synthetic fuels should be reported under the category **"Other transformation processes"**. The consumption of hydrogen and synthetic fuels should be reported under the corresponding sectors. This could be inputs to electricity and/or heat plants or final consumption sectors including non-energy use. The fuel or electricity inputs should be reported under the corresponding column in *Row Y (Memo: Input to Hydrogen & synthetic fuels production)*. Refer to *Row Y* under section *ROWS* below for more details.

The addition of this memo item outside the balance provides a mean to enhance the granularity for reporting supply and demand of these energy carriers without a risk of

double counting or breaking the balance, until a harmonized methodology for reporting is adopted in international energy statistics.

**Column R: "Memo: Heat pumps"** is a memo category outside the current main structure of the energy balance. The addition of this memo item allows the reporting of data corresponding to all types of heat pumps and not only large-scale units used for selling heat which are currently reported in the main balance. The reporting under this Memo category should not impact the existing means of reporting data corresponding to large-scale heat pumps as part of the main energy balance. Refer to *Row A (Production)*, *Row K (Own use and losses)*, *Row I (Electricity, CHP and heat plants)* and *ROW W (Heat generated)* for details on how to report heat pumps as part of the main structure of the energy balance.

For reporting under this memo category, the ambient heat extracted from the environment should be reported under "**Production**". The net heat output (gross output - ambient heat), which equals the electricity input should be reported under the item "**Other transformation processes**". The consumption of heat from the heat pumps should be reported under the specific sector(s). The electricity and non-ambient heat (e.g. recovered heat) inputs should be reported under the corresponding columns in *Row Z (Memo: Input to heat pumps)*. Refer to *Row Z* under section *ROWS* below for more details.

## Rows

**Row A: "Production"** shows only production of primary energy, i.e. hard coal and lignite, oil shale, peat, biofuels and renewable waste (see definition above), non-renewable waste, crude oil and NGL, natural gas, and electricity and heat from nuclear, hydro, tidal, wave, geothermal, wind and solar plants. Note that:

- (a) Where synthetic liquid or gas hydrocarbons are produced directly as a result of "in place extraction" they should be regarded as primary fuels and included under production. For example, oil from tar sands and shale should be shown in *Column C (oil)*.
- (b) Production of natural gas should exclude gas reinjected, vented or flared but should include gas subsequently used in the gas extraction and drying processes as well as for transportation of the gas by pipeline.
- (c) Heat from large-scale only (heat pumps which sell heat to third parties) that is extracted from the ambient air is included in the heat column under this category.

**Row B/C: "Imports (+)" and "Exports (-)"** show trade both in primary and secondary forms of energy. Note in particular that LPG traded should be placed in *Column C (oil)*. Nuclear fuel trade is not shown in the balance. Trade in electricity is counted at the same heat value as in final consumption (1 TWh = 0.086 Mtoe). For countries trading across common borders, actual import and export figures should be given instead of a net trade balance.

**Row D: "International marine bunkers"** includes those quantities of fuel delivered to ships of all flags that are engaged in international navigation. The international navigation may take place at sea, on inland lakes and waterways, and in coastal waters. The domestic/international split is determined on the basis of port of departure and port of arrival, and not by the flag or nationality of the ship. Consumption by ships engaged in

domestic navigation is not covered here but should be included in *Row O* under the transport sector.

**Row E: "International aviation bunkers"** includes deliveries of aviation fuels to aircraft for international aviation. Fuels used by airlines for their road vehicles are excluded. The domestic/international split should be determined on the basis of departure and landing locations and not by the nationality of the airline. Consumption by aircraft engaged in domestic aviation are not covered here but should be included in *Row O* under the transport sector.

**Row F: "Stock changes"** show additions to stocks as negative, and lowering of stock levels as positive. For the projection years, stock changes are conventionally zero. However, countries may report the data if available. The reporting of this category is optional and not part of the mandatory reporting for projection years.

**Row G: "Total energy supply" (TES)** is made up of production (*Row A*), imports (*Row B*, positive), exports (*Row C*, negative), international marine bunkers (*Row D*, negative), international aviation bunkers (*Row E*, negative) and stock changes (*Row F* either positive or negative).

Note that when no stock change data is submitted (optional reporting), the TES is still populated with the assumption of a zero value for the stock change figure.

**Row H: "Transformation processes and energy industry own use"** shows the total of the energy transformation processes (*Rows I* and *J*) and energy used by energy-producing industries and losses in energy distribution, transmission and transport (*Row K*).

**Row I: "Electricity, CHP and heat plants"** *Cells IA* to *IL* in this table should contain inputs of each fuel for the production of electricity and heat as negative entries. This row includes both main activity producer (formerly known as public)<sup>3</sup> and autoproducer<sup>4</sup> plants. However, for autoproducers all fuel inputs to electricity production are taken into account, while only the part of fuel inputs to heat sold is shown. Note that fuel inputs for the production of heat consumed within the autoproducer's establishment are not included here but are included with figures for the final consumption of fuels in the appropriate consuming sector.

Outputs of electricity appear as a positive number in *Cell IM* and the heat that is sold to outside users appears as a positive number in *Cell IN*. Transformation losses are shown as negative numbers in the **"Total"** column, *Cell IO*.

Note that Gross electricity produced should contain total electricity generation in Mtoe calculated on the basis of 1 TWh = 0.086 Mtoe. Gross generation from hydro plants should not include that generated by pumped storage. The energy absorbed for pumped

---

<sup>3</sup> Main activity producers generate electricity and/or heat for sale to third parties, as *their primary activity*. They may be privately or publicly owned. Note that the sale need not take place through the public grid.

<sup>4</sup> Autoproducer undertakings generate electricity and/or heat, wholly or partly for their own use as an activity which *supports* their primary activity. They may be privately or publicly owned.

storage should be accounted for under **"Own use and losses"**, Row K. Refer to *Column F (Hydro)* above for more details.

Note that if electricity is being used to produce heat in large-scale heat pumps used to sell heat or electric boilers, the electricity inputs should be reported in *Cell IM*. Similarly the corresponding net heat output (gross output - ambient heat in case of the heat pumps) should be reported in *Cell IN*.

**Row J: "Other transformation processes"** includes conversion losses in gas manufacture, oil refineries, coke ovens and blast furnaces, liquefaction, and other non-specified transformation.

Hydrogen or other synthetic fuels produced from hydrocarbons (e.g. natural gas), would be shown as secondary oil production in *Cell JC*. Refer to *Column C (Oil)* above for more details.

**Row K: "Own use and losses"** contains the primary and secondary energy consumed by transformation industries for heating, pumping, traction and lighting purposes. These are shown as negative numbers. Included here are, for example, coal mines' own use of energy, power plants' own consumption (which includes net electricity consumed for pumped storage), and energy used for oil and gas extraction. Also includes losses in gas distribution, electricity transmission and coal transport. Note the following:

- (a) Fuels used for pipeline transport should be included in the transport sector.
- (b) The electricity generation losses appear in the electricity, CHP and heat plants.
- (c) If hydrogen or synthetic fuels are produced through power to gas process by consumption of electricity, and due to the current absence of these products in the main structure of the energy balance, the conversion losses should be accounted under **"Own use and losses"**. Refer to *Column M (Electricity)* above for more details.

**Row L: "Statistical differences"**. In principle, the figure for total requirements should equal the sum of deliveries to final consumption and use for transformation and consumption within the energy sector plus losses. However, in practice this is rarely the case and the difference is shown as **"Statistical differences"**. This arises because the data for the individual components of supply are often derived from different data sources by the national administrations. Furthermore, the inclusion of changes in some large consumers' stocks in the supply part of the balance introduces distortions which also contribute to the statistical difference.

**Row M: "Total Final Consumption" (TFC)** is the sum of consumption by the different end-use sectors and also includes non-energy use. Backflows from the petrochemical industry are not included in final consumption. TFC can be derived from both formulas below:

TFC = industry + transport + other + non-energy use, and

TFC = TES + transformation processes and energy industry own use + statistical differences.

**Row N: "Industry"** sector should cover all activity in mining, manufacturing and construction except for fuel production and transformation sectors. The industry's use of

energy for own transport should be included under the **"Transport"** category. The use of coke oven and blast furnace gas by the iron and steel industry appears in the form of coal and coal product consumption and not as gas. Feedstocks to the chemical/petrochemical industry should not be included in this category. Refer to *Row T (Non-energy use)* below for more details.

**Row O: "Transport"** sector includes all fuels for transport regardless of sector, except international marine bunkers and international aviation bunkers. Fuels used for pipeline transport should be included here.

**Row P: "Of which: Road"** sub-sector includes all fuels for road transport regardless of sector. This includes fuels used in road vehicles as well as agricultural and industrial highway use. This category excludes military consumption and diesel oil for use in tractors that are not for highway use.

**Row Q: "Other"** covers the sum of consumption in residential, commercial/public services, agriculture/forestry, fishing and military use.

**Row R: "Of which: Residential"** includes consumption by households, excluding fuels used for transport.

**Row S: "Of which: Commercial and public services"** includes consumption corresponding to commercial and public services.

**Row T: "Non-energy use"** includes coal, oil and gas that are not used for energy purposes, such as bitumen, lubricants, waxes, white spirit and that part of petroleum coke which cannot be used for energy purposes. Non-energy use of peat and biomass should not be included here. The use of petrochemical feedstocks in the chemical/petrochemical industry should be included here and not under industry.

Note that natural gas used for ammonia production, which converts to hydrogen during the process, should be reported under this category.

**Row U: "Of which chemical/petrochemical"** covers the use of petrochemical feedstocks in the chemical/petrochemical industry.

**Row V: "Electricity generated excluding pumped storage"** shows total quantities of gross electricity generated in TWh by all electricity and CHP plants. Electricity generated from pumped storage should not be included. Refer to *Row I* above for more details.

**Row W: "Heat generated (PJ)"** shows quantities of heat produced for sale by CHP and heat plants. Heat produced in electric boilers should be reported under the product **"Electricity"** and heat produced by large-scale heat pumps should be reported under the product **"Heat"**.

**Row X: "Memo: Electrical capacities (MW)"** represents the net maximum capacity which is the maximum active power that can be supplied, continuously, with all plant running, at the point of outlet (i.e. after taking the power supplies for the station auxiliaries

and allowing for the losses in those transformers considered integral to the station). Please refer to the Annual electricity data questionnaire instructions<sup>5</sup> for more details.

**Row Y: "Memo: Input to Hydrogen & synthetic fuels production"** is a memo category outside the current main structure of the energy balance. This memo flow has been added to allow reporting the data corresponding to fuel/electricity inputs for hydrogen and synthetic fuels production in a more visible manner. However, the reporting under this Memo category should not impact the existing means of reporting inputs to hydrogen and synthetic fuels production as part of the main energy balance. Refer to *Column A (Coal/Oil shale)*, *Column D (Natural gas)* and *Column M (Electricity)* for details on how to report these inputs in the main structure of the energy balance.

For reporting under this memo category, the input for the production of synthetic fuels should be reported under the respective column. For example, the coal input should be reported in *Cell ZA*. If hydrogen production is from natural gas reforming, then the input should be reported in *Cell ZD*. Similarly, for power to gas processes (e.g. electrolysers), the electricity input should be reported under the product **"Electricity"** in *Cell ZM*. The production and consumption of hydrogen and synthetic fuels should be reported under the *Column Q (Memo: Hydrogen & synthetic fuels)*. For details refer to *Column Q* above.

The addition of this memo item outside the balance provides a mean to enhance the granularity for reporting supply and demand of these energy carriers without a risk of double counting or breaking the balance, until a harmonized methodology for reporting is adopted in international energy statistics

**Row Z: "Memo: Input to heat pump"** is a memo category outside the current main structure of the energy balance. The addition of this memo item allows the reporting of input data corresponding to all types of heat pumps and not only large-scale units used for selling heat which are currently reported in the main balance. The reporting under this Memo category should not impact the existing means of reporting the input corresponding to large-scale heat pumps as part of the main energy balance. Refer to *Row A (Production)* and *Row I (Electricity, CHP and Heat Plants)* for details on how to report large-scale heat pumps inputs as part of the main structure of the energy balance.

For reporting under this memo category, the electricity used to generate heat in all types of heat pumps, including the small-scale residential ones which are not used for commercial purposes, should be reported under *Column M (Electricity)*. Moreover, any non-ambient heat (e.g. recovered heat) used as an input to heat pumps; should be reported under *Column N (heat)*. The ambient heat input, the net heat output and consumption of heat produced from the heat pumps should be reported under the memo product **"Memo: Heat pumps"**. For more details please refer to *Column R* above.

---

<sup>5</sup> [https://iea.blob.core.windows.net/assets/92c8e9d6-b8b1-4ecc-a0da-f3c00f5f0f42/Electricity\\_HeatQuestionnaire\\_Instructions.pdf](https://iea.blob.core.windows.net/assets/92c8e9d6-b8b1-4ecc-a0da-f3c00f5f0f42/Electricity_HeatQuestionnaire_Instructions.pdf).

## Units and conversions

This section outlines the units and conversion factors which should be used when completing the energy balance (Table 1). The full methodological details on how to complete Table 1 is detailed in the section "Table 1- Energy Balances" above.

The energy balances should be completed in millions of tonnes (metric tons) of oil equivalent (Mtoe). 1 Mtoe = 41.868 Petajoules (10 Petacalories). In converting fuels to Mtoe for the purpose of the energy balances and other tables, respondents should use the factors outlined below.

### Oil

The same default net calorific values used to convert oil products in reporting through the Oil annual questionnaire should be used for conversion. These figures are region-specific and are expressed in kJ/kg as shown below:

Default NCVs (kJ/kg)			
Product	Europe	America	Asia Oceania
Refinery gas	49 500	48 100	48 100
Ethane	49 500	49 400	49 400
LPG	46 000	47 300	47 700
Aviation gasoline	44 000	44 800	44 600
Motor gasoline	44 000	44 800	44 600
Jet gasoline	43 000	44 800	44 600
Jet kerosene	43 000	44 600	44 500
Other kerosene	43 000	43 800	42 900
Naphtha	44 000	45 000	43 200
Gas/diesel oil	42 600	42 600	42 600
Fuel oil	40 000	40 200	42 600
Petroleum coke	32 000	32 000	33 800
White spirit	43 600	43 000	43 000
Lubricants	42 000	42 000	42 900
Bitumen	39 000	40 000	38 800
Other oil products	40 000	40 000	40 000

Crude oil (including NGL, refinery feedstocks, additives and "other hydrocarbons") production, imports and direct use should be converted using the specific net calorific

value of the crude oil(s), NGL, feedstocks, additives and "other hydrocarbons" for the country concerned. The NCVs used should be the same as those reported on the Annual Oil Questionnaire. If you are unable to get a copy of what was submitted, please contact [slt@iea.org](mailto:slt@iea.org).

## Coal

Coal has separate net calorific values for production, imports, exports, inputs to electricity/heat generation and coal used in coke ovens, blast furnaces and industry.

The net calorific values used for the various coals and coal products that make up production, trade and consumption should be the same as those given in the Coal (solid fossil fuels and manufactured gases) Annual Questionnaire. If you are unable to get a copy of what was submitted, please contact [slt@iea.org](mailto:slt@iea.org). As data for gas derived from coal are usually provided in TJ, the problem of specific net calorific values does not arise.

Note that the data for the coal gases in Mtoe should be derived from net heat values. To calculate the net heat content of a gas from its gross heat content, multiply the gross heat content by the appropriate following factor.

Gas works gas	0.9
Coke oven gas	0.9
Blast furnace gas	1.0
Other recovered gases	1.0

## Natural gas

Gas data provided in joules should be converted as follows: 1 Mtoe = 41 868 TJ.

Data should be converted from 1000 m<sup>3</sup> to Terajoules using the country-specific factors given in the Natural Gas Annual Questionnaire. [The average net heat value of 1000 m<sup>3</sup> of gas = 0.034 Terajoules.]

To calculate the net heat content of natural gas from its gross heat content, the gross heat content should be multiplied by 0.9.

## Nuclear

The primary energy value ascribed to nuclear electricity is calculated from the gross generation by assuming that only 33% of the primary energy content appears as electricity. The calculation to be carried out is the following: Gross electricity generation in TWh x 0.086 / 0.33 = primary energy equivalent in Mtoe.

Heat sold by nuclear power plants should be shown as an output in the heat column (positive number in *Cell IN*), with an identical input in the nuclear column (negative number in *Cell IE*).

## Hydro

The primary energy value ascribed to hydroelectricity is the energy content of the gross electricity generation from the natural flow of the water course: Gross generation from hydroelectric plants, excluding that from pumped storage plants: Gross electricity generation in TWh x 0.086 = primary energy equivalent in Mtoe.

## Wind

The primary energy value ascribed to electricity produced from wind is taken to be the physical energy content of the gross generation: Gross electricity generation in TWh x 0.086 = primary energy equivalent in Mtoe.

## Geothermal

If information on geothermal heat inputs to electricity generation is not available, then the primary energy value ascribed to geothermal electricity is calculated from the gross generation by assuming that only 10% of the primary energy content appears as electricity. The calculation to be carried out is the following: Gross electricity generation in TWh x 0.086 / 0.10 = primary energy equivalent in Mtoe.

For heat production, the indigenous production of geothermal is the difference between the enthalpy of the fluid produced in the production borehole and that of the fluid eventually disposed of (re injection borehole). Heat sold by geothermal plants should be shown as an output in the heat column (positive number in *Cell IN*), with the input in the geothermal column (negative number in *Cell IH*). If the actual geothermal plant efficiency is not known, then the primary equivalent is calculated assuming an efficiency of 50%. The calculation to be carried out is the following: Heat production in TJ x 0.00002388 / 0.50 = primary energy equivalent in Mtoe.

## Solar

Solar includes both solar photovoltaic electricity generation and solar thermal electricity and heat generation.

The primary energy value ascribed to electricity produced from solar photovoltaic is taken to be the physical energy content of the gross generation: Gross electricity generation in TWh x 0.086 = primary energy equivalent in Mtoe.

The primary energy equivalent for solar thermal energy is the heat available to the heat transfer medium, i.e. the incident solar energy less the optical, collectors and other eventual losses. It should be reported as indigenous production. The quantity of heat consumed should be entered in the relevant final sectors.

For electricity produced from solar thermal heat, unless the actual efficiency is known, the primary equivalent is calculated assuming an efficiency of 33%. The calculation to be carried out is the following: Gross electricity generation in TWh x 0.086 / 0.33 = primary energy equivalent in Mtoe. For heat produced in a solar thermal plant, the primary equivalent is equal to the heat consumed, i.e. 1 TJ = 0.00002388 Mtoe.

## Tide/Wave/Ocean Energy, etc.

The primary energy value ascribed to electricity produced from tide, wave, ocean and other non-thermal sources is taken to be the physical energy content of the gross generation: Gross electricity generation in TWh x 0.086 = primary energy equivalent in Mtoe.

## Biofuels and Renewable Wastes

Data that are provided in joules in the Renewables and Waste Annual Questionnaire should be converted as follows: 1 Mtoe = 41 868 TJ.

Data for charcoal and liquid biofuels (both reported in 1 000 tonnes) should be converted using an appropriate country-specific factor.

## Non-Renewable Wastes

Data that are provided in joules in the Renewables and Waste Annual Questionnaire should be converted as follows: 1 Mtoe = 41 868 TJ.

## Electricity

Electricity is converted as follows: 1 TWh = 0.086 Mtoe.

## Heat

Heat is converted as follows: 1 Mtoe = 41 868 TJ.

## Memo: Offshore Wind

As for the total Wind, the primary energy value ascribed to electricity produced from wind is taken to be the physical energy content of the gross generation: Gross electricity generation in TWh x 0.086 = primary energy equivalent in Mtoe.

## Memo: Hydrogen & synthetic fuels

As hydrogen and other synthetic fuels produced through transformation and consumed across sectors are typically in their pure form rather than a mixture, their calorific values can be easily identified based on their respective chemical formula. For Hydrogen net calorific value of 120 MJ/kg should be used for the purpose of reporting. The net calorific values used for these fuels should be the same as those used when submitting the respective data in the Oil and Natural Gas Annual Questionnaires. If you are unable to get a copy of what was submitted, please contact [slt@iea.org](mailto:slt@iea.org).

## Memo: Heat pumps

Heat is converted as follows: 1 Mtoe = 41 868 TJ.

## Table 2 – Supplementary data

This table includes macroeconomic data and is should be submitted for the provisional year (year 2020 for this cycle) and projection years. The included categories are detailed below:

**"GDP growth rates (%)"** represents the average annual growth rates of GDP. The annual growth rates refer to GDP in constant prices and should be calculated as detailed below:

- For historical and provisional year report the  $GDP_{year}/GDP_{year-1}$  annual rate.
- For the projections years report the  $GDP_{year}/GDP_{year-10}$  average annual rate. Note that this average should be calculated as a geometric mean. For instance the 2020 to 2030 period the average growth rates is calculated as:

$$\text{Average annual GDP growth rate}_{2030/2020} = \left( \frac{GDP_{2030}}{GDP_{2020}} \right)^{\left( \frac{1}{10} \right)} - 1$$

**"Population (millions)"** represents the national population in millions.

**"GDP (billion USD 2015)"** represents GDP in constant 2015 prices.

Note: The Secretariat will update the GDP and population figures submitted with those published in OECD National Accounts prior to the publication of the database.

## Table 3 – Emission savings from CCUS

Decarbonizing the energy system can only be achieved with a broad suite of technologies. Carbon capture, utilization and storage (CCUS) is considered one of the components of the future technology mix as it will allow reducing emissions across hard-to-abate sectors. Hence, CCUS has become a critical part of long-term strategies for achieving energy and climate targets.

This table should be used to report any emission savings associated with CCUS across the energy supply, transformation and consumption sectors. The data should be reported for latest three historical years, the provisional year as well as projections.

Data should be reported in kilo tonnes of CO<sub>2</sub> avoided (ktCO<sub>2</sub>). The table includes the following categories:

**“Total”** represents the total emission savings through CCUS across the energy landscape.

**“Natural gas processing”** represents the emission savings through CCUS at natural gas processing plants.

**“Manufacturing”** represents the emission savings associated with CCUS across the manufacturing sectors, including ammonia production, Iron and steel and cement production.

**“Electricity and heat generation”** represents the emission savings associated with CCUS in power generation.

**“Hydrogen and synthetic fuel production”** represents the emission savings associated with CCUS in the production of blue hydrogen and other synthetic fuels.

**“Other”** represents the emission savings associated with CCUS in other areas of the energy supply, transformation and consumption not defined above.

## CSV Import and Export

The data compilers have an option to import and export the data in CSV format. This could be a useful tool to automatize the data import and easily extract the data in a desired format. The details on how to use these functions are outlined below.

Note: **if multiple scenarios are available**, the user can save this questionnaire / extract the corresponding csv, then change the scenario and report the data for the alternative scenario (s). This scenario information will be included in the exported CSV file.

### Importing projections data from CSVs

The data providers can load data from a CSV file to fill the tables for projections. The CSV import function is included on the “**Data Import & Export**” tab.

In order to import the data using this function, the CSVs prepared for import should include the data with code names which match the structure of the data included in the questionnaire. The table below lists the corresponding codes for all of the Products and Flows included in all three tables of the questionnaire.

FLOWS	
<b>Table 1</b>	
Long name	Code
Production (+)	INDPROD
Imports (+)	IMPORTS
Exports (-)	EXPORTS
International marine bunkers (-)	MARBUNK
International aviation bunkers (-)	AVBUNK
Stock changes (±)	STOCKCHA
Total energy supply	TES
Transformation processes & Energy industry own use	TRANENER
Electricity, CHP & heat plants (±)	ELECHEAT
Other transformation processes (±)	TRANOTH
Own use and Losses	OWNUSE
Statistical differences (±)	STATDIFF
Total Final Consumption	TFC
Industry (+)	TOTIND
Transport (+)	TOTTRANS
of which: Road (+)	ROAD

Other (+)	TOTOTHER
of which: Residential (+)	RESIDENT
of which: Commercial and Public Services (+)	COMMPUB
Non-energy use (+)	NONENUSE
of which: chemical/petrochemical (+)	NECHEM
Elec. Gen. Exc. Pumped storage (TWh) (+)	ELOUTPUT
Heat generated (PJ) (+)	HEATOUT
Memo: Electrical capacities (MW)	ELECAP
Memo: Input to Hydrogen & Synthetic fuels production	INH2PROD
Memo: Input to Heat pump	INHEATPUMP

**Table 2**

Long name	Code
GDP Growth Rates (%)	GDPGR
Population (Millions)	POPULATION
GDP (billion USD 2015)	GDP

**Table 3**

Long name	Code
Total	CCTOTAL
Natural gas processing	CCNGPROC
Manufacturing	CCMANUFACT
Electricity and heat generation	CCELECHEAT
Hydrogen and synthetic fuel production	CCH2PROD
Other	CCOTHER

## PRODUCTS

**Table 1**

Long name	Code
Coal / Oil shale	COAL
Peat	PEAT
Oil	OIL
Natural gas	NATGAS

Nuclear	NUCLEAR
Hydro	HYDRO
Wind	WIND
Geothermal	GEO THERM
Solar	SOLAR
Tide, Etc.	TIDEOTHER
Biofuels & renewable waste	COMRENEW
Non-renewable waste	NRENWASTE
Electricity	ELECTR
Heat	HEAT
Total	TOTAL
Memo: Offshore Wind	MWINDOFF
Memo: Hydrogen & Synthetic fuels	MH2SYNFUEL
Memo: Heat pump	MHEATPUMP

**Table 2**

Long name	Code
N/A	TOTAL

**Table 3**

Long name	Code
N/A	TOTAL

In order to use CSV import function the steps listed below should be followed:

For importing the projections data corresponding to Table 1 and Table 3:

- On the **“Data Import & Export”** tab and in cell B10, indicate the import file path in the following format: *“C:/xxx/xxxx”*, e.g. *“C:/Users/Dupont/Documents”*.
- Prepare and place a CSV file including the projections data corresponding to Table 1 and Table 3 in the following format considering the codes as listed in the table above:

*“Country”, “Scenario”, “Product”, “Flow”, “2030”, “2040”, “2050”*

*e.g. “Australia”, “Baseline”, “COAL”, “INDPROD”, “100”, “60”, “30”*

*e.g. “Australia”, “Baseline”, “TOTAL”, “CCTOTAL”, “1200”, “800”, “1600”*

- Click on the **“Import energy projections (Table 1 &3)”** button.

For importing the projections data corresponding to Table 2:

- On the **“Data Import & Export”** tab and in cell B10, indicate the import file path in the following format: *“C:/xxx/xxxx”*, e.g. *“C:/Users/Dupont/Documents”*.
- Prepare and place a CSV file including the projections data corresponding to Table 2 in the following format considering the codes as listed in the table above:

*“Country”, “Scenario”, “Product”, “Flow”, “2030”, “2040”, “2050”*

*e.g. “Australia”, “Baseline”, “TOTAL”, “GDPGR”, “2”, “3”, “4”*

- Click on the **“Import macro-economic projections (Table 2)”** button.

Following the above steps, the forecast data will be copied in the three data tables.

## Exporting projections data in CSVs

Similarly, the data providers can export the data corresponding to the projections data in a CSV format. This includes the respective data included in all three tables. The CSV export function is included on the **“Data Import & Export”** tab. In order to use this function the steps listed below should be followed:

- On the **“Data Import & Export”** tab and in cell B12, indicate the export file path in the following format: *“C:/xxx/xxxx/”*, e.g. *“C:/Users/Dupont/Documents/”*.
- Click on the **“Export all projections”** button.

Following the above steps, a CSV which includes all the projections data includes in the three tables, will be saved in the indicated location, under the name *“Country.csv”*, e.g. *“Australia.csv”*.

## 5. Energy transitions indicators and graphs

A new functionality allows to populate various indicators and produce graphics based on the reported data, to support data validation and better tracking across historical and projection periods.

Accurate and up-to-date indicators are essential to assess how countries energy systems are evolving and to identify gaps and opportunities for policy decisions. No single indicator can fully capture the complexity of energy transitions; however, if taken together, a set of indicators can unpack the underlying drivers of energy supply and demand changes, and the energy sector's contribution to greenhouse gas (GHG) emissions.

This section describes the underlying methodology for deriving the transition indicators presented within the questionnaire on the **"Indicators"** sheet, to help with interpretation.

The indicators and their graphical representations are divided into three main categories including: i) Energy production and consumption; ii) GHG emissions from fuel combustion; iii) Electricity/heat generation and emissions; as detailed below. Please note that GHG emissions estimations are only provided as benchmark estimate and do not replace official national submissions.

By clicking on the respective links located on the top left hand side of the **"Indicators"** sheet, users can navigate through the page to view the corresponding tables and graphical representation included for each indicator.

### Energy production and consumption

This section includes a set of transition indicators which correspond to energy supply and consumption including sectoral disaggregation.

The indicators listed below are taken directly from the data submitted in Table 1. However, the energy units have been all converted to units of joules in an effort to facilitate analysis and comparison with other sources.

- **Production by source (TJ)**
- **Total Energy Supply (TES) by source (TJ)**
- **Total Final Energy Consumption (TFEC) by fuel (TJ)**
- **Total consumption by sector (TJ)**
- **Industry energy consumption by source (TJ)**
- **Transport energy consumption by source (TJ)**
- **Road transport energy consumption by source (TJ)**
- **Other sectors energy consumption by source (TJ)**
- **Residential energy consumption by source (TJ)**
- **Commercial and public services energy consumption by source (TJ)**
- **Non-energy use by source (TJ)**
- **Electricity consumption by sector (EJ)**
- **Heat consumption by sector (EJ)**
- **Total input to electricity, CHP & heat plants (TJ)**

The following listed indicators are derived from the data submitted in Table 1 and Table 2 as detailed below:

- **Energy intensity of the economy (MJ per USD):**

Similar to the Sustainable Development Goal (SDG) 7.3.1 indicator, this indicator is measured in terms of primary energy supply and GDP as a proxy for energy efficiency. Note that due to the availability of the data submitted in the questionnaire, the GDP used for deriving this indicator is represented in constant terms at exchange rates. However, the official SDG 7.3.1 indicator is measured in constant terms at purchasing power parities<sup>6</sup>.

This indicator is calculated as:

$$\text{Energy Intensity} = \frac{TES}{GDP}$$

Where:

*TES*: Total energy supply (reported in Table 1)

*GDP*: Gross Domestic Product (extrapolated based on the average annual growth rate reported in Table 2 and the latest available absolute figure available from the OECD National accounts).

- **Final Consumption per GDP (MJ per USD)**

This indicator is calculated as:

$$\text{Final consumption per GDP} = \frac{TFC}{GDP}$$

Where:

*TFC*: Total Final Consumption (reported in Table 1)

*GDP*: Gross Domestic Product (extrapolated based on the average annual growth rate reported in Table 2 and the latest available absolute figure available from the OECD National accounts).

- **Energy supply per capita (GJ per Capita)**

This indicator is calculated as:

$$\text{Energy supply per capita} = \frac{TES}{\text{Population}}$$

Where:

*TES*: Total energy supply (reported in Table 1)

*Population*: National population (reported in Table 2)

- **Final consumption per capita (GJ per Capita)**

This indicator is calculated as:

$$\text{Final consumption per capita} = \frac{TFC}{\text{Population}}$$

---

<sup>6</sup> For more information on the methodology, please refer to the official SDG 7.3.1 metadata available at: <https://unstats.un.org/sdgs/metadata/files/Metadata-07-03-01.pdf>.

Where:

*TFC*: Total Final Consumption (reported in Table 1)

*Population*: National population (reported in Table 2)

- **Other non-specified energy consumption by source (TJ)**

This indicator represents the final energy consumption excluding industry, transport, residential and commercial and public services sectors. In other words it includes the energy consumption corresponding to agriculture/forestry, fishing and final consumption not elsewhere specified.

The indicator is derived as

$$\begin{aligned} \text{Other non – specified energy consumption}_p & \\ &= \text{Other sectors energy consumption}_p \\ &- (\text{Residential energy consumption}_p \\ &+ \text{Commerical and public services energy consumption}_p) \end{aligned}$$

Where:

*Other sectors energy consumption<sub>p</sub>*: Final consumption of all end-use sectors besides Industry and transport of energy product *p* (reported in Table 1)

*Residential energy consumption<sub>p</sub>*: Residential consumption of energy product *p* (reported in Table 1)

*Commerical and public services energy consumption<sub>p</sub>*: Commercial and public services consumption of energy product *p* (reported in Table 1)

- **Energy self-sufficiency (%)**

Self-sufficiency is an indicator representing the portion of the total energy demand which is met by the Indigenous production and can be used as a proxy to understand the country's dependence on energy imports.

This indicator is calculated as

$$\text{Self sufficiency}_p = \frac{\text{Production}_p}{\text{TES}_p}$$

Where:

*Production<sub>p</sub>*: Indigenous production of energy product *p*. This includes "Oil", "Coal/Oil Shale and Peat", "Natural gas" and "Total" (reported in Table 1)

*TES<sub>p</sub>*: Total energy supply of energy product *p* (reported in Table 1)

- **Renewables energy share in total energy supply (%):**

This indicator represents the share of renewable sources in total energy supply and is calculated as

$$\%TES_{RES} = \frac{TES_{RES}}{TES_{TOTAL}}$$

Where:

$TES_{Total}$ : Total energy supply of all energy products (reported in Table 1)

$TEC_{RES}$ : Total energy supply of renewable energy sources which includes: hydro, wind, solar, geothermal, tide, etc. and biofuels and renewable waste (reported in Table 1)

- **Renewable energy share in the total final energy consumption (%) (SDG 7.2.1):**

The indicator is used to track SDG 7.2, which is to increase substantially the share of renewable energy in the global energy mix by 2030. The indicator is derived using the same methodology corresponding to the official SDG 7.2.1 indicator which is defined as the share of renewable energy in total final energy consumption.

The denominator is the total final energy consumption of all energy products (as defined in Table 1) while the numerator, the renewable energy consumption, is a series of calculations defined as: the direct consumption of renewable energy sources plus the final consumption of gross electricity and heat that is estimated to have come from renewable sources. This estimation allocates the amount of electricity and heat consumption to renewable sources based on the share of renewables in gross production in order to perform the calculation at the final energy level<sup>7</sup>.

This indicator is calculated as

$$\%TFEC_{RES} = \frac{TFEC_{RES} + \left(TFEC_{ELE} \times \frac{ELE_{RES}}{ELE_{TOTAL}}\right) + \left(TFEC_{HEAT} \times \frac{HEAT_{RES}}{HEAT_{TOTAL}}\right)}{TFEC_{TOTAL}}$$

Where:

$TFEC_{TOTAL}$ : Total final energy consumption is the sum of final energy consumption in the transport, industry, and other sectors (also equivalent to the total final consumption minus non-energy use)

$TFEC_{RES}$ : Direct final energy consumption of renewable energy sources which include hydro, wind, solar, geothermal, tide, etc. and biofuels and renewable waste (reported in Table 1)

$TFEC_{ELE}$ : Final consumption of gross electricity (reported in Table 1)

$TFEC_{HEAT}$ : Final consumption of gross heat (reported in Table 1)

$ELE$ : Gross electricity production (reported in Table 1)

$HEAT$ : Gross heat production (reported in Table 1)

- **Fossil energy share in energy supply (%):**

This indicator represents the share of fossil fuels in total energy supply and is calculated as

$$\%TES_{FOS} = \frac{TES_{FOS}}{TES_{TOTAL}}$$

<sup>7</sup> For more information on the methodology, please refer to the official SDG 7.2.1 metadata available at: <https://unstats.un.org/sdgs/metadata/files/Metadata-07-02-01.pdf>.

Where:

$TES_{Total}$ : Total energy supply of all energy products (reported in Table 1)

$TEC_{FOS}$ : Total energy supply of fossil fuels which include coal/oil shale, peat, oil, natural gas and non-renewable waste (reported in Table 1)

- **Fossil energy share in final energy consumption (%):**

This indicator is calculated as

$$\%TFEC_{FOS} = \frac{TFEC_{FOS} + \left( TFEC_{ELE} \times \frac{ELE_{FOS}}{ELE_{TOTAL}} \right) + \left( TFEC_{HEAT} \times \frac{HEAT_{FOS}}{HEAT_{TOTAL}} \right)}{TFEC_{TOTAL}}$$

Where:

$TFEC_{TOTAL}$ : Total final energy consumption is the sum of final energy consumption in the transport, industry, and other sectors (also equivalent to the total final consumption minus non-energy use)

$TFEC_{FOS}$ : Direct final energy consumption of fossil fuels which include coal/oil shale, peat, oil, natural gas and non-renewable waste (reported in Table 1)

$TFEC_{ELE}$ : Final consumption of gross electricity (reported in Table 1)

$TFEC_{HEAT}$ : Final consumption of gross heat (reported in Table 1)

$ELE$ : Gross electricity production (reported in Table 1)

$HEAT$ : Gross heat production (reported in Table 1)

## Greenhouse gas (GHG) emissions from fuel combustion

This section includes a set of transition indicators which include estimated GHG emissions and respective indicators.

The included historical GHG emissions from fuel combustion are taken directly from the IEA global database of [greenhouse gas emissions from energy](#). These estimates are obtained following harmonised definitions and comparable methodologies across countries. They do not represent an official source for national submissions, as national administrations should use the best available country specific information to complete their emissions reporting.

The estimated emission figures for projection years are derived based on the submitted total energy supply data by fuel category in the questionnaire. More details are provided in the following sections.

The following listed indicators are derived from the data submitted in Table 1 and Table 2 as detailed below:

- **CO<sub>2</sub> and GHG emissions from fuel combustion by source (Mt CO<sub>2</sub> and Mt CO<sub>2eq</sub>)**

CO<sub>2</sub> from fuel combustion presents total CO<sub>2</sub> emissions from fuel combustion. This includes CO<sub>2</sub> emissions from fuel combustion in *IPCC Source/Sink Category 1 A Fuel Combustion Activities* and those, which may be reallocated to *IPCC Source/Sink Category 2 Industrial Processes and Product Use* under the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*. Similarly GHG from fuel combustion presents total greenhouse gas emissions from fuel combustion including CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O corresponding to the same IPCC categories.

Note that according to the *2006 IPCC Guidelines*, CO<sub>2</sub> emissions from combustion of biofuels and renewable waste are not included in the emission estimates from energy; while, the associated non-CO<sub>2</sub> (CH<sub>4</sub> and N<sub>2</sub>O) emissions are taken into account. However, the GHG estimates included in this tool, exclude the non-CO<sub>2</sub> emissions from combustion of renewable sources, which in the case of the IEA member countries correspond to a minor percentage of total emissions from fuel combustion.

For the historical years the estimates are demand-based estimates from the IEA global database of [greenhouse gas emissions from energy](#), where The IEA uses the (Tier 1) methodology to estimate GHG emissions from fuel combustion based on the *2006 IPCC Guidelines*. For more details on the underlying methodology please refer to the respective [database documentation file](#).

However for the projection years and due to the absence of demand side data, the indicators are derived based on the submitted total energy supply data by fuel category in the questionnaire, and the respective average fuels-specific carbon intensities for the latest three historical years as detailed below:

$$CO_2 \text{ or GHG Emissions from fuel combustion by source} = \sum_p TES_p \times EF_{p,y} \quad (1)$$

Where:

*Emissions*: Total GHG emissions (expressed in Mt CO<sub>2eq</sub>) or CO<sub>2</sub> only emissions (expressed in Mt CO<sub>2</sub>)

$EF_p$ : Emission factors of fossil energy product  $p$  expressed in CO<sub>2</sub> / TJ or in CO<sub>2eq</sub> / TJ

However, given that the fossil energy products “Oil”, “Coal/Oil Shale and Peat” and “Other” reported in the questionnaire aggregate different products with various emission factors, an average emission factor based on the average mix of products from the last 3 years is calculated, according to the following formula:

$$EF_{p,y} = \frac{1}{3} \sum_i \left[ \left( \frac{Emissions_{p,y-1}}{TES_{p,y-1}} \right) + \left( \frac{Emissions_{p,y-2}}{TES_{p,y-2}} \right) + \left( \frac{Emissions_{p,y-3}}{TES_{p,y-3}} \right) \right]$$

Where:

$EF_{p,y}$ : Average emission factors for product  $p$  (applied in the calculation (1) for projection years)

$p$ : Aggregate product “Oil”, “Coal/Oil Shale and Peat” and “Other”. Note that “Natural gas” product refers to one single standard emission factor in the 2006 IPCC Guidelines.

$Emissions_{p,y-1/y-2/y-3}$ : Total GHG (or CO<sub>2</sub> only) demand based emission estimates of the aggregated fuel  $p$  from the latest three historical years.

$TES_{p,y-1/y-2/y-3}$ : Total energy supply of aggregated fuel  $p$  from the latest three historical years

- **CO<sub>2</sub> and GHG emissions from fuel combustion by final consumption sectors (Mt CO<sub>2</sub> and Mt CO<sub>2eq</sub>)**

Similar to the total CO<sub>2</sub> (GHG) from fuel combustion as outlined above, the sectoral emissions include emissions corresponding to *IPCC Source/Sink Category 1 A Fuel Combustion Activities* and those, which may be reallocated to *IPCC Source/Sink Category 2 Industrial Processes and Product Use* under the 2006 IPCC Guidelines.

For the historical years the estimates are demand-based estimates from the IEA global database of [greenhouse gas emissions from energy](#), where The IEA uses the (Tier 1) methodology to estimate GHG emissions from fuel combustion based on the 2006 IPCC Guidelines and the sectoral consumption data.

However for the projection years and due to the absence of demand side data, the indicators are derived based on the submitted sectoral consumption data by fuel category in the questionnaire, and the respective sectoral average carbon intensities for the latest three historical.

$$Emissions_i = \sum_p FC_{i,p} * EF_{p,y} \quad (1)$$

Where:

$FC_{i,p}$ : Final consumption of fossil energy product  $p$  in sector  $i$  (from Table 1).

$EF_{p,y}$ : Average emission factors for product  $p$  (applied in the calculation (1) from year  $y$  onwards)

$$EF_{p,y} = \frac{1}{3} \sum_p \left[ \left( \frac{Emissions_{p,y-1}}{FC_{p,y-1}} \right) + \left( \frac{Emissions_{p,y-2}}{FC_{p,y-2}} \right) + \left( \frac{Emissions_{p,y-3}}{FC_{p,y-3}} \right) \right]$$

Where:

$p$ : Aggregate product "Oil", "Coal/Oil Shale and Peat" and "Other". Note that "Natural gas" product refers to one single standard emission factor in the 2006 IPCC Guidelines.

$Emissions_{p,y-1/y-2/y-3}$ : Sectoral GHG (or CO<sub>2</sub> only) demand based emission estimates of the aggregated fuel  $p$  from the latest three historical years.

$FC_{p,y-1/y-2/y-3}$ : Final sectoral consumption of aggregated fuel  $p$  from the latest three historical years

- **CO<sub>2</sub> and GHG emissions from fuel combustion per capita (tonnes CO<sub>2</sub>/Cap and tonnes CO<sub>2eq</sub> / Cap)**

This indicator is calculated as

$$Emissions\ per\ capita = \frac{Emissions}{Population}$$

Where:

*Emissions*: Total GHG (expressed in Mt CO<sub>2eq</sub>) or CO<sub>2</sub> emissions (expressed in Mt CO<sub>2</sub>) from fuel combustion (estimated per above methodology)

*Population*: National population (reported in Table 2)

- **CO<sub>2</sub> and GHG emissions from fuel combustion per GDP (kg CO<sub>2</sub>/USD and kg CO<sub>2eq</sub>/USD)**

This indicator is calculated as

$$Emissions\ per\ GDP = \frac{Emissions}{GDP}$$

Where:

*Emissions*: Total GHG (expressed in Mt CO<sub>2eq</sub>) or CO<sub>2</sub> emissions (expressed in Mt CO<sub>2</sub>) from fuel combustion (estimated per above methodology)

*GDP*: Gross Domestic Product (extrapolated based on the average annual growth rate reported in Table 2 and the latest available absolute figure available from the OECD National accounts).

- **CO<sub>2</sub> and GHG emissions per energy consumption (tonnes CO<sub>2</sub>/TJ and tonnes CO<sub>2eq</sub>/TJ)**

$$Emission\ intensity\ of\ the\ energy\ mix = \frac{Emissions}{TES_{Total}}$$

Where:

*Emissions*: Total GHG (expressed in Mt CO<sub>2eq</sub>) or CO<sub>2</sub> emissions (expressed in Mt CO<sub>2</sub>) from fuel combustion (estimated per above methodology)

$TES_{Total}$ : Total energy supply of all energy products (reported in Table 1)

- **CO<sub>2</sub> emissions and drivers indices and LMDI decomposition**

Decomposition of CO<sub>2</sub> emissions from fuel combustion into four driving factors (Kaya decomposition), can be represented as below. However, it should be noted that there are

important caveats in the use of the Kaya identity. Most important, the four terms on the right-hand side of equation should be considered neither as fundamental driving forces in themselves, nor as generally independent from each other.

$$C = P \times \frac{GDP}{P} \times \frac{TES}{GDP} \times \frac{C}{TES}$$

Where:

$C$ : Total CO<sub>2</sub> emissions from fuel combustion

$P$ : National population (reported in Table 2)

$\frac{GDP}{P}$ : GDP/population

$\frac{TES}{GDP}$ : Total energy supply per GDP (energy intensity of the economy)

$\frac{C}{TES}$ : Emissions intensity of the energy mix

The Kaya identity expresses, for a given time, CO<sub>2</sub> emissions as the product of population, per capita economic output (GDP/P), energy intensity of the economy (TES/GDP) and carbon intensity of the energy mix (C/TES). For the purpose of this analysis the driving forces are represented as Indices (2017=100). Because of possible non-linear interactions between terms, the sum of the percentage changes of the four factors, e.g.  $(P_y - P_x)/P_x$ , will not generally add up to the percentage change of CO<sub>2</sub> emissions  $(C_y - C_x)/C_x$ . However, relative changes of CO<sub>2</sub> emissions in time can be obtained from relative changes of the four factors as follows:

$$\frac{C_y}{C_x} = \frac{p_y}{p_x} \times \frac{\left(\frac{GDP}{P}\right)_y}{\left(\frac{GDP}{P}\right)_x} \times \frac{\left(\frac{TES}{GDP}\right)_y}{\left(\frac{TES}{GDP}\right)_x} \times \frac{\left(\frac{C}{TES}\right)_y}{\left(\frac{C}{TES}\right)_x}$$

Where:

$x$  and  $y$  represent two different years.

The effect of each coefficient is then expressed in unit of CO<sub>2</sub> emissions (Mt CO<sub>2</sub>) by applying the logarithmic mean divisia (LMDI) method proposed by Ang (2004)<sup>8</sup>. Using this method, the change in total CO<sub>2</sub> emissions from fuel combustion ( $\Delta C_{Total}$ ) between year  $t$  and a base year 0, can be computed as the sum of the changes in each of the individual factors as follows:

$$\Delta C_{Total} = \Delta C_p + \Delta C_{GDP/P} + \Delta C_{TES/GDP} + \Delta C_{C/TES}$$

The effect of the variation of each coefficient on the total emission is then calculated by applying the LMDI formula:

---

<sup>8</sup> B. W. Ang, Decomposition analysis for policymaking in energy: which is the preferred method? Energy Policy, 32 (9) (2004), pp. 1131–1139

$$\Delta C = \sum_i w_{i,t} \ln\left(\frac{A_{i,t}}{A_{i,0}}\right)$$

$$\text{with } w_{i,t} = L(\text{Emissions}_{i,0}, \text{Emissions}_{i,t})$$

Where:

$A_{i,t}$  : level of coefficient  $i$  at time  $t$

$$L(X_1, X_2) = \frac{X_2 - X_1}{\ln\left(\frac{X_2}{X_1}\right)} \text{ if } X_1 \neq X_2 \text{ and } L(X_1, X_1) = X_1$$

In this decomposition, each effect can therefore be calculated as

$$\Delta C_p = L(C^t, C^0) \ln\left(\frac{p^t}{p^0}\right)$$

$$\Delta C_{GDP/P} = L(C^t, C^0) \ln\left(\frac{\left(\frac{GDP}{P}\right)^t}{\left(\frac{GDP}{P}\right)^0}\right)$$

$$\Delta C_{TES/GDP} = L(C^t, C^0) \ln\left(\frac{\left(\frac{TES}{GDP}\right)^t}{\left(\frac{TES}{GDP}\right)^0}\right)$$

$$\Delta C_{C/TES} = L(C^t, C^0) \ln\left(\frac{\left(\frac{C}{TES}\right)^t}{\left(\frac{C}{TES}\right)^0}\right)$$

## Electricity/heat generation and emissions

This section includes a set of transition indicators which correspond to electricity and heat generation and corresponding GHG emissions.

The two indicators listed below are taken directly from the data submitted in Table 1.

- **Electricity output by source (TWh)**
- **Heat output by source (PJ)**

The following listed indicators are derived from the data submitted in Table 1 as detailed below:

- **Share of Renewable sources in electricity and heat generation (%)**

The below two indicators, represent the share of renewable sources in electricity and heat generation respectively and are calculated as

$$\text{Renewable share}_{ELE} = \frac{ELE_{RES}}{ELE_{TOTAL}} \text{ and } \text{Renewable share}_{HEAT} = \frac{HEAT_{RES}}{HEAT_{TOTAL}}$$

Where:

$ELE_{TOTAL}$ : Total electricity generation excluding pumped storage (reported in Table 1)

$ELE_{RES}$ : Electricity generation from renewable energy sources (reported in Table 1)

$HEAT_{TOTAL}$ : Total heat generation (reported in Table 1)

$HEAT_{RES}$ : Heat generation from renewable energy sources (reported in Table 1)

$RES$ : Renewable Energy Sources, which include: "Hydro", "Wind", "Geothermal", "Solar", "Tide, Etc." and "Biofuels & renewable waste".

- **Share of low-carbon sources in electricity and heat generation (%)**

The below two indicators, represent the share of low-carbon sources in electricity and heat generation respectively and are calculated as

$$\text{Low carbon share}_{ELE} = \frac{ELE_{Low\ carbon}}{ELE_{TOTAL}} \text{ and } \text{Low carbon share}_{HEAT} = \frac{HEAT_{Low\ carbon}}{HEAT_{TOTAL}}$$

Where:

$ELE_{TOTAL}$ : Total electricity generation excluding pumped storage (reported in Table 1)

$ELE_{LowCarbon}$ : Electricity generation from low-carbon energy sources (reported in Table 1)

$HEAT_{TOTAL}$ : Total heat generation (reported in Table 1)

$HEAT_{LowCarbon}$ : Heat generation from low-carbon energy sources (reported in Table 1)

*Low carbon*: Low-carbon energy sources, which include all renewables sources as defined above plus "Nuclear"

- **Electricity and heat generation CO<sub>2</sub> and GHG emissions from fuel combustion (Mt CO<sub>2</sub> and Mt CO<sub>2eq</sub>)**

Similar to the total and sectoral CO<sub>2</sub> (GHG) from fuel combustion as outlined above, the electricity and heat generation emissions include emissions corresponding to *IPCC Source/Sink Category 1 A Fuel Combustion Activities* and those, which may be reallocated to *IPCC Source/Sink Category 2 Industrial Processes and Product Use* under the *2006 IPCC Guidelines*.

For the historical years the estimates are demand-based estimates from the IEA global database of [greenhouse gas emissions from energy](#), where The IEA uses the (Tier 1) methodology to estimate GHG emissions from fuel combustion based on the *2006 IPCC Guidelines* and the inputs to the power generation plants.

However for the projection years and due to the absence of demand side data, the indicators are derived based on the submitted input to generation plants data by fuel category in the questionnaire, and the respective power generation average carbon intensities for the latest three historical.

$$Emissions = \sum_p C_p * EF_{p,y} \quad (1)$$

Where:

$C_p$ : Inputs of electricity, CHP and heat plants from aggregated fossil product  $p$  (from Table 1)

$EF_{p,y}$ : Average power generation emission factors for product  $p$  (applied in the calculation (1) for projection years)

$$EF_{p,y} = \frac{1}{3} \sum_p \left[ \left( \frac{Emissions_{p,y-1}}{C_{p,y-1}} \right) + \left( \frac{Emissions_{p,y-2}}{C_{p,y-2}} \right) + \left( \frac{Emissions_{p,y-3}}{C_{p,y-3}} \right) \right]$$

Where:

$p$ : Aggregate product “Oil”, “Coal/Oil Shale and Peat” and “Other”. Note that “Natural gas” product refers to one single standard emission factor in the *2006 IPCC Guidelines*.

$Emissions_{p,y-1/y-2/y-3}$ : Power generation GHG (or CO<sub>2</sub> only) demand based emission estimates of the aggregated fuel  $p$  from the latest three historical years.

$C_{p,y-1/y-2/y-3}$ : Inputs of electricity, CHP and heat plants from aggregated fossil product  $p$  from the latest three historical years

- **Intensity of electricity and heat generation (ton/MJ)**

This indicator is derived from the fuel combustion emissions associated with electricity and heat generation and the electricity and heat output from the plants. The indicator is calculated as below for the historical and projection years respectively.

For **historical** years:

$$Intensity_{Electricity \& \text{ heat}} = \frac{\sum_p \text{electricity and heat emissions}_p}{Output_{Electricity \& \text{ heat}}}$$

Where:

$Electricity \text{ and heat emissions}_p$ : Demand-based estimates from the IEA global database of [greenhouse gas emissions from energy](#), for aggregated product  $P$

$Output_{Electricity \& \text{ heat}}$ : Total output of electricity and heat plants from all sources

For **projection** years:

$$Intensity_{Electricity \& \text{ heat}} = \frac{\sum_p (Input_{electricity, \text{ CHP \& heat plants}})_p \times EF_p}{Output_{Electricity \& \text{ Heat}}} \quad (1)$$

Where:

$Input_{electricity, \text{ CHP \& heat plants}, p}$ : Input of aggregated product  $p$  in electricity, CHP & heat plant

$Output_{Electricity \& \text{ heat}}$ : Total output of electricity and heat plants from all sources

$EF_{p,y}$ : Average emission factors for product  $p$  (applied in the calculation (1) for projection years)

$$EF_{p,y} = \frac{1}{3} \sum_i \left[ \left( \frac{Emissions_{p,y-1}}{C_{p,y-1}} \right) + \left( \frac{Emissions_{p,y-2}}{C_{p,y-2}} \right) + \left( \frac{Emissions_{p,y-3}}{C_{p,y-3}} \right) \right]$$

Where:

$p$ : Aggregate product "Oil", "Coal/Oil Shale and Peat" and "Other". Note that "Natural gas" product refers to one single standard emission factor in the 2006 IPCC Guidelines.

$Emissions_{p,y-1/y-2/y-3}$ : Electricity and heat generation GHG (or CO<sub>2</sub> only) demand based emission estimates of the aggregated fuel  $p$  from the latest three historical years.

$C_{p,y-1/y-2/y-3}$ : Input of aggregated fuel  $p$  into electricity, CHP & heat plant from the latest three historical years

- **Electricity and heat emissions and drivers indices and LMDI decomposition**

Similar to the indicators derived for total emissions from fuel combustion, the following Kaya identity can be used to decompose the evolution of the emissions related to electricity and heat generation into four main factors. This decomposition expresses, for a given time, CO<sub>2</sub> emissions from electricity and heat generation as the product of the carbon intensity of the fossil fuel mix ( $CF$ ), the reciprocal of fossil fuel based thermal electricity and heat generation efficiency ( $1/EI$ ), the share of electricity from fossil fuels ( $FS$ ) and total electricity and heat output ( $EH$ ).

$$C = (CF) (EI) (FS) (EH)$$

Where

$C = Emissions_{Electricity \& \text{ heat}}$ : Emissions from electricity and heat generation

$CF = \sum_p \frac{Input_{electricity, \text{ CHP \& heat plants}, p} \times EF_p}{Input_{electricity, \text{ CHP \& heat plants}, p}}$ : Carbon intensity of the fossil fuel mix

$EI = \sum_p \frac{Input_{electricity, \text{ CHP \& heat plants}, p}}{Output_{Electricity \& \text{ heat}, p}}$ : The reciprocal of fossil fuel based electricity and heat generation efficiency

$FS = \frac{Output_{Electricity \& \text{ heat}, fossil}}{Output_{Electricity \& \text{ heat}}}$ : Share of electricity and heat from fossil fuel and non-renewable waste

$EH = Output_{Electricity \& \text{ Heat}}$ : Total electricity and heat output

Similar to the Kaya identity expressed for total fuel combustion emissions, due to non-linear interactions between terms, if a simple decomposition is used, the sum of the

percentage changes of the four factors may not perfectly match the percentage change of total CO<sub>2</sub> emissions. Hence, the (LMDI) method proposed by Ang (2004)<sup>9</sup> has been used. Using this method, the change in total CO<sub>2</sub> emissions from electricity and heat generation ( $\Delta C_{Total}$ ) between year  $t$  and a base year  $0$ , can be computed as the sum of the changes in each of the individual factors as follows:

$$\Delta C_{Total} = \Delta C_{CF} + \Delta C_{EI} + \Delta C_{FS} + \Delta C_{EH}$$

The effect of the variation of each coefficient on the total emission is then calculated by applying the LMDI formula:

$$\Delta C = \sum_i w_{i,t} \ln \left( \frac{A_{i,t}}{A_{i,0}} \right)$$

$$\text{with } w_{i,t} = L(\text{Emissions}_{i,0}, \text{Emissions}_{i,t})$$

Where :

$A_{i,t}$  : level of coefficient  $i$  at time  $t$

$$L(X_1, X_2) = \frac{X_2 - X_1}{\ln \left( \frac{X_2}{X_1} \right)} \text{ if } X_1 \neq X_2 \text{ and } L(X_1, X_1) = X_1$$

In this decomposition, each effect can therefore be calculated as

$$\Delta C_{CF} = L(C^t, C^0) \ln \left( \frac{CF^t}{CF^0} \right)$$

$$\Delta C_{EI} = L(C^t, C^0) \ln \left( \frac{EI^t}{EI^0} \right)$$

$$\Delta C_{FS} = L(C^t, C^0) \ln \left( \frac{FS^t}{FS^0} \right)$$

$$\Delta C_{EH} = L(C^t, C^0) \ln \left( \frac{EH^t}{EH^0} \right)$$

---

## Geographical notes

Country/Region	Short name	Definition
Australia	AUSTRALI	Excludes the overseas territories. Data are reported on a fiscal year basis. By convention data for the fiscal year that starts on 1 July Y-1 and ends on 30 June Y are labelled as year Y.
Austria	AUSTRIA	
Belgium	BELGIUM	
Canada	CANADA	
Denmark	DENMARK	Excludes Greenland and the Faroe Islands, except prior to 1990, where data on oil for Greenland were included with the Danish statistics.
Estonia	ESTONIA	Data start in 1990. Prior to that, they are included within Former Soviet Union.
Finland	FINLAND	
France	FRANCE	Includes Monaco and excludes the overseas collectivities: New Caledonia; French Polynesia; Saint Barthélemy; Saint Martin; Saint Pierre and Miquelon; and Wallis and Futuna. Energy data for the following overseas departments: Guadeloupe; French Guiana; Martinique; Mayotte; and Réunion are included for the years from 2011 onwards, and excluded for earlier years.
Germany	GERMANY	Includes the new federal states of Germany from 1970 onwards.
Greece	GREECE	
Hungary	HUNGARY	Data start in 1965.
Ireland	IRELAND	
Israel	ISRAEL	The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law. Data start in 1971. Israel is currently seeking accession to full IEA membership (Accession country), therefore it is included in the IEA and Accession/Association countries aggregate (IEA Family), for data starting in 1971 and for the entire time series.
Italy	ITALY	Includes San Marino and the Holy See.
Japan	JAPAN	Includes Okinawa. Starting 1990, data are reported on a fiscal year basis. By convention data for the fiscal year that starts on 1 April Y and ends on 31 March Y+1 are labelled as year Y.
Korea	KOREA	Data start in 1971.

Lithuania	LITHUANIA	Lithuania is currently seeking accession to full IEA membership (Accession country), therefore it is included in the IEA and Accession/Association countries aggregate (IEA family), for data starting in 1990 and for the entire time series. Data for Lithuania are available starting in 1990. Prior to that, they are included in Former Soviet Union.
Luxembourg	LUXEMBOU	
Mexico	MEXICO	Data start in 1971.
Netherlands	NETHLAND	Excludes Suriname, Aruba and the other former Netherland Antilles (Bonaire, Curaçao, Saba, Saint Eustatius and Sint Maarten).
New Zealand	NZ	
Norway	NORWAY	
Oman	OMAN	
Poland	POLAND	
Portugal	PORTUGAL	Includes the Azores and Madeira.
Slovak Republic	SLOVAKIA	Data start in 1971.
Slovenia	SLOVENIA	Data start in 1990. Prior to that, they are included within Former Yugoslavia.
Spain	SPAIN	Includes the Canary Islands.
Sweden	SWEDEN	
Switzerland	SWITLAND	Includes Liechtenstein for the oil data. Data for other fuels do not include Liechtenstein.
Turkey	TURKEY	
United Kingdom	UK	Shipments of coal and oil to the Channel Islands and the Isle of Man from the United Kingdom are not classed as exports. Supplies of coal and oil to these islands are, therefore, included as part of UK supply. Exports of natural gas to the Isle of Man are included with the exports to Ireland. As of the 1st of February 2020, the United Kingdom (UK) is no longer part of the European Union (EU) and has entered into a transition period until 31 December 2020. In this publication with data up to 2019, the UK is still included in the EU28 aggregate. However, it is excluded from the EU27_2020 aggregate.
United States	USA	Includes the 50 states and the District of Columbia but generally excludes all territories, and all trade between the U.S. and its territories. Oil statistics include Guam, Puerto Rico <sup>10</sup> and the United States Virgin Islands; trade statistics for coal include international trade to and from Puerto Rico and the United States Virgin Islands. Starting with 2017 data, inputs to and outputs from electricity and heat generation include Puerto Rico.

<sup>10</sup> Inputs to and outputs from electricity and heat generation up to 2016, and natural gas data for the entire time series for Puerto Rico are included under Other non-OECD Americas.

Memo: European  
Union - 27

EU27\_2020

Refers to the EU28 aggregate with the exclusion of the United Kingdom.  
Namely includes Austria; Belgium; Bulgaria; Croatia; Cyprus<sup>11</sup>; the Czech Republic; Denmark; Estonia; Finland; France; Germany; Greece; Hungary; Ireland; Italy; Latvia; Lithuania; Luxembourg; Malta; the Netherlands; Poland; Portugal; Romania; the Slovak Republic; Slovenia; Spain and Sweden. Please note that in the interest of having comparable data, all these countries are included since 1990 despite different entry dates into the European Union.

## Abbreviations

Btu: British thermal unit

CCUS: Carbon capture, utilisation and storage

GWh: gigawatt hour

kcal: kilocalorie

kg: kilogramme

kJ: kilojoule

Mt: million tonnes

m<sup>3</sup>: cubic metre

PJ: petajoule

t: metric ton

TWh: terawatt hour

TJ: terajoule

toe: tonne of oil equivalent

GCV: gross calorific value

GHGs: Greenhouse gases

HHV: higher heating value = GCV

LHV: lower heating value = NCV

NCV: net calorific value

CHP: combined heat and power

PPP: purchasing power parity

TES: total energy supply

IEA: International Energy Agency

OECD: Organisation for Economic Co-operation and Development

SDG: Sustainable Development Goals
