European Experience With Energy Management

Paul Waide
Waide Strategic Efficiency Ltd

IEA Workshop on energy management and digital technologies Benefits, Prospects, Barriers and Policies, Paris, December 12th, 2017
EM in Europe traces its roots to the 1970s

- Following the 1970s oil shocks many countries promoted energy audits in industry
- Mixed outcomes as audit recommendations were often not acted upon; however, energy efficiency improved
- The need to address organisational culture regarding the management of energy became clearer and in particular to address the split incentive between capital equipment procurement account holders and O&M account holders
- National EM practices were developed from 1990 to 2010
- National standards began to be merged into European standards from about 2005 onwards
- These informed ISO’s EM standards beginning with ISO 50001 in 2011
Enabling policy environments

- Green energy taxes in many EU Member States from ~2000 onwards
- EU Emissions Trading Scheme from 2005
- Support for audits
- Support for energy efficient investments
- Long term agreements
- Energy efficiency networks
- Energy efficiency Directive
Policy - The four principal EE Directives

EU directives on energy efficiency

- Ecodesign Directive
- Energy Labelling Directive
- Energy Efficiency Directive

From 2012
The EED requires Member States to make energy audits mandatory for large enterprises and gives the possibility for enterprises that have implemented broader energy management schemes such as ISO 50001 to be exempt. It also provides incentives for SMEs to have audits.

Nonetheless it leaves several important gaps:

a) it does not oblige or encourage affected enterprises to implement an energy management system (just to conduct audits)

b) it does not oblige or encourage affected enterprises to implement cost effective measures identified in the audits

c) it does not create a system to support the adoption and implementation of energy management systems

d) mandatory audits only apply to large enterprises
Other policies implemented at MS level

Incentives and obligations feature in the most visibly effective programmes

- **long term voluntary agreement (LTAs)** schemes operated by Denmark, Finland, Flanders, Ireland, Netherlands, Sweden and UK, wherein participating enterprises agree to reduce their energy intensity or CO$_2$ emissions by pre-agreed amounts over a certain period

- In each case the authorities have created an incentive to participate in these schemes through access to more favourable tax regimes; often via lower energy or carbon taxes
Example - the Dutch Long Term Agreements

Energy efficiency improvement for various sectors under LTA1

Annual energy savings under the LTA2 by type (PE = process efficiency, SE = systems efficiency, EEPD = supply chain efficiency)

Germany’s energy tax incentives

- A tax on electricity payable by firms was introduced in Germany in 2007 and set at €205/MWh

- Until 2012 companies that paid more than €1000/year for this tax were eligible to apply for a 90% reduction; however, in 2013 the exemption eligibility rules were amended such that companies are now **obliged to prove that they have an energy management system** certified to DIN EN 16001 or DIN EN ISO 50001 in place to be eligible to receive the tax discounts

- As of 2014 about 25000 firms were eligible to receive tax reductions that totalled 2.3 billion Euros in value, and about 3000 EN ISO 50001 certifications were undertaken in early 2014

- DE has the highest certified uptake of EN ISO 50001 in the world
Audit incentives and EE networks

• France, Finland, Germany, Norway, Sweden and the UK amongst others have provided direct financial and technical assistance to conduct energy audits and implement energy saving measures in the industrial sector and sometimes the service sector

• Germany, Ireland and Sweden operate extensive (subsidised) energy efficiency networks to provide peer to peer support in implementing EE in businesses

Trends in the no. of EN ISO 50001 certified organisations by European country

- EED mandatory audits (or EM) from December 2015
EN ISO 50001 certifications as a share of ISO 9001 certifications by country in 2015
Distribution of EN ISO 50001 certification by European industry sector in 2015

Distribution by type:
- 34% Heavy
- 54% Light
- 10% Services
Overall levels of adoption of EM

5.2% of medium to large European companies had adopted EN ISO 50001 in 2016 (up from 2.8% in 2015)

- The no. of EM certified organisations grew by 69% in 2016
- Many organisations have EM but are not certified or don’t use ISO50001
- there is a broad spectrum of behaviours currently seen but on average EM adoption is still well below economically rational levels
- energy intensive and larger organisations are much more likely to have adopted proactive energy management strategies
- very few organisations adopt strategies to realise all financially attractive measures and even less to optimise their climate impact
- the case of no systematic energy planning predominates in SMEs
- short term profit maximisation is most common in other commercial enterprises such that measures with payback periods of beyond 2 years are seldom considered

Waide Strategic Efficiency
Conclusions

- certification to EN ISO 50001 is growing quite rapidly from a low base
- motivation to be certified is driven by economic incentives (stimulated by public policy) resulting in a major asymmetry in the level of certification by EU Member State
- awareness of energy management and its significance is increasing yet most organisations are struggling to implement it effectively
- they tend to operate conservative, risk-averse strategies that avoid deflecting time and effort from core business activities
- given this situation there remains a considerable scope to develop more sophisticated EM strategies that mine the cost effective savings potentials more fully
Complementary slides
Findings from a recent study published on Leonardo Energy

Assesses the state of EM in the EU covering:

• industry and building sectors
• adoption levels and current practice
• drivers and barriers
• impacts, costs and savings potentials
• policy experiences
Summary of key findings

- EM accesses systemic energy savings opportunities that are very difficult to capture through other means
- Current EM adoption rates are far below cost-effective levels
- Better and more widely adopted Energy Management has the potential to save ~26% of EU combined energy use in the industrial and service sectors of which 19% could be delivered through more robust policies
- Average net cost savings of €53 billion per annum to 2035 and average CO₂ emissions savings of 165 Mt CO₂/year
- Current policy frameworks, such as the encouragement for audits in the Energy Efficiency Directive are helpful but need to be strengthened to deliver
- More robust and holistic policy approaches are required
The **Optimal Scenario**, which assumes economically-optimised EM, leads to some 1 728 Mtoe of cumulative energy savings from 2016 to 2035 of which:

- 807 Mtoe of savings are in industry and 931 Mtoe of savings are in the tertiary sector
- This equates to estimated cumulative CO$_2$ savings of 4.8 gigatonnes over the same period with annual savings of 383 million tonnes of CO$_2$ in 2035
- Extra investments of €119 billion in equipment and related services are needed at an average of €6.0 billion per year to deliver these savings
- These are over fourteen times less than the value of the energy bill savings, which total €1 684 billion over the period, at an average of €84 billion per year
Industrial sector savings under the Optimal Scenario compared with the Reference Scenario
Following review of the EED the Commission and MS should consider amending the provisions which currently exclusively concern energy audits to:

- introduce **MS level targets for the share of enterprises that have adopted EM** and where the targets are set based on the proportion of enterprises of a given size and energy intensity within each MS

- consider amending the EED energy audit obligations to become an **obligation to adopt a full energy management system** for enterprises using more than a minimum prescribed energy consumption or energy intensity level and above a minimum size

- set **MS targets for the number of certified energy managers**, wherein the targets are proportional to the economy’s size and energy intensity and increase to a plateau with time
THE SCOPE FOR ENERGY SAVING FROM ENERGY MANAGEMENT
